August 1992

Video Information System Overview

Industry Assessment

The mass consumer market has eluded computer information products. While personal computers have become pervasive in business and to a lesser degree in education, fewer than 25% of U.S. households own a personal computer -- after 15 years. We believe this is primarily because computers simply don't do the kinds of things people want to do in the mainstream part of their time at home and today's computers don't operate in a manner suitable for many home environments. Today, computers are used primarily for utility based applications (word processing, data and financial analysis, data management, and communication). The user supplies information and the computer stores, processes, and presents it in modified form. The user must expend a great deal of effort learning to use the utility and then entering information before any real benefit is derived. This is not the model that most people operate under in the home. At home we are consumers of information. We plug in a tape or disc and listen to music, read a book, or push a button and watch TV. In these cases, we are not required to create information before we consume it.

In traditional personal computing, the user must learn how to communicate with the computer. Information must be translated into a form the computer can understand and then information from the computer must be translated into something the human can deal with. This translation process is the responsibility of the user. This means that the user must learn how to deal with information on computer terms. The translation steps required for people to communicate with computers create complexity and a greater chance for errors and frustration. To many consumers in the home, it's just not worth it.

The opportunity is enormous for products that deliver compelling and relevant information to the user with a minimum of effort. At Tandy, we refer to the concept of basing products primarily on their ability to deliver information in a simple, productive, and even fun way as the *content based* model (versus a "utility based" model). The content model functions more like other information products the consumer uses in the home. Audio, video, books, magazines, television, and newspapers are all content based products that focus on the delivery and consumption of information. The characteristic elements for these home information products are that very little initial effort is required, they are easy to use, and there is an enormous variety of information to choose from. Combining the content model with technology that provides interactivity, user control and navigational aids, provides an opportunity to deliver existing information and new forms of information to the home in better ways.

In personal computing, the industry is based on relatively few categories of tools (spreadsheets, word processors, data management, and data communication applications). This works because the user supplies most of the information that is personally relevant and the computer manipulates the information. In formats where the user does not supply the information, there are hundreds of categories and thousands of titles to choose from. Just look at the average book, music, or video store for confirmation. Content based product classes must rely on a huge infrastructure of information creation, gathering, and publishing to make them successful.

We are witnessing the birth of a very rapidly expanding industry infrastructure to deliver information in digital form. Consumer technology is moving to digital forms of information (digital representations of text, music, voice, pictures, video, etc.) delivered through digital delivery methods (CD-Audio, Digital Compact Cassette, CD-ROM, digital telephony, High-Definition Television, expanded cable television, and direct broadcast satellite). Developments in the multimedia personal computing industry have brought information providers from the traditional publishing and production industries into the picture as they seek to "re-purpose" their content into new markets and provide novel approaches for users to "consume" their information.

Tandy is applying the developments in information delivery technology and the movement toward creating a diverse pool of digital information in creating a unique product class. These products will provide a window to the world of digital information for the mass consumer. The goal is to provide a platform to deliver content to the typical mass consumer. This must be done in a way that provides user selection, control, and navigation for an enormous amount and variety of information delivered through electronic channels and digital media. The benefits of this information can be derived by the consumer with a minimum of initial effort and the information will be delivered on terms that the user can understand – human terms.

Using the latest developments in multimedia information delivery, the user will interact with the system using pictures, voice, music, animations – representations that do not require learning or translation. This not only minimizes the effort versus benefit relation, it also reduces the chances of errors in communication and understanding. The content originator can create an experience for the ultimate consumer that more clearly represents the concepts and messages that were intended.

Several attempts have been made at presenting products to the mass consumer market that target this opportunity. These approaches fall into three camps. One approach is to take the relatively successful home video game concept and attach a device (CD-ROM) that is capable of delivering a higher volume of digital data. The current implementations of this approach have added some additional data to the titles, but have failed to position the content delivery into the wide variety of categories required for the mass information market. This has not catalyzed new types of delivery or information. These products have simply augmented the existing repertoire of game software. These systems deal with computer generated information only (animations, synthesized music,...) and do not have

the capability of delivering a wide range of "natural" human information (high fidelity music and voice, high quality images, and sophisticated methods of control and navigation through large sources of information). While these systems may be successful in the enhanced game category, we do not expect them to have a significant long term success in the consumer information market.

The second approach is the "Trojan Horse" concept. This takes a personal computer and (partially) hides it within a consumer case. An example of this approach is CDTV from Commodore. This is essentially an Amiga computer packaged in a product that looks like a CD player or VCR on the front and a computer on the back. The concept is to use the existing base of Amiga software in a CD-ROM based product that is presumably more palatable to the mass consumer. The CDTV system was introduced in 1991 with limited acceptance. We believe the primary reasons for this timid reaction from consumers is that it has a schizophrenic personality to the consumer (part computer, part consumer product), the Amiga software base is not CD-ROM oriented and therefore did not take advantage of the key advantages of digital information delivery, CDTV is weak in certain key video and audio capabilities, and it has a limited software infrastructure on which to base a significant push toward broad content based title development. We do not expect CDTV to be a significant factor in this product category.

The third approach is to design a product from scratch optimized for the consumer market without constraining the internal architecture to existing computer architectures and industry infrastructures. CD-I from Philips is an example of such an approach. This seems very compelling at first glance. The consumer doesn't care what's on the inside, so focus on the product design from their perspective. This is a great theory -- in practice, however, it assumes that a significant industry movement and infrastructure can be built around a unique architecture.

The CD-I design was originated in 1985 with the "Greenbook" specification using technology and concepts that were appropriate for the mid-1980's. The display technology is designed for standard TV presentation. CD-I uses two audio types, CD-Audio and a compressed form of audio play that allows other information (like digital pictures) to be played from the CD at the same time. The CD-I architecture is highly focused on playing "streams" of images with audio. This lends itself to slide show and talking story type titles that do not require a high degree of simultaneous action and interactivity. On the outside, Philips has positioned CD-I as a "player" to deliver custom applications to a target market of families with young children.

Philips needed a variety of titles aimed at their target market. To accomplish this, they have used a model we will refer to as the "studio model". If you must create new types of titles for a new type of architecture, it is very difficult to convince a large number of developers and publishers to invest their own funds in development without an installed base of devices that can play them. New tools will have to be developed to do the work. Developers must learn how to develop for a unique architecture. The economics must justify investing limited discretionary software development funds on a platform that does

not exist considering the same funds could be invested in development for titles that have a much more predictable return on investment. The studio model says that a "platform sponsor" (Philips in this case) will create the equivalent of a movie studio and provide funding, direction, and control for the titles that are developed. The studio handles distribution and owns all or part of the equity in the title. The theory is that if you commit enough financial resources, this model will provide a seed group of titles to get things rolling, develop an installed base of product, providing a jump start to the platform. In 1986, Philips created and funded American Interactive Media (AIM) to create titles for CD-I. After six years and enormous financial investment by Philips, CD-I was launched to the consumer market in 1991 with approximately 40 titles. CD-I has experienced limited acceptance in the marketplace since the introduction last fall.

Philips has been actively seeking other hardware participants for the platform. They have had limited success in enlisting a few companies to produce products for the Japanese market, primarily in the commercial application area. Currently there are no other consumer electronics manufacturers promoting CD-I in the US and European markets.

In the seven years since CD-I was designed, there have been significant advances in technology and dramatic changes in the industry. In the late 1980's, multimedia technology moved to the forefront of leading edge personal computing technology and is moving rapidly to mainstream functionality. At the same time, the consumer technology arena has made a significant shift from analog based to digital based technologies. Personal communication is also moving rapidly toward the digital realm. The technology to collect, process, and deliver digital content has evolved very rapidly since the mid-1980's. The primary display devices of the future will be digital and use higher resolutions than the TV systems that CD-I supports today.

There is a serious dilemma in gaining installed based to support software infrastructure versus maintaining broad industry support and competition. For example, if Philips drops the price for CD-I to increase the installed platform base, they will alienate other potential hardware suppliers who can not afford to sell CD-I products competitively. Since these other companies don't own the studio, they can not make up the difference with software sales. This will limit distribution and customer perception of industry-wide participation. On the other hand, with a low installed base of platforms, the economics will not justify title development where the incremental cost and complexity of moving it from or to another platform are very high. While CD-I has compelling attributes, we do not think that the technology or the industry support for CD-I is sufficient to sustain it as a mainstream consumer product in the long term.

These three approaches exist because there is a huge potential market for the right products. The demographic group representing the primary target for introducing these platforms (baby boomer families that are technology oriented with appropriate income levels) represent over six million households in the US alone. Two million of those households are categorized as very early adopters of new technologies. This target

market has been much more elusive than either Philips or Commodore expected. The cool response is not for lack of funding or effort.

It is unlikely that any of these first generation approaches will gain industry-wide acceptance for the following reasons:

1. They do not leverage the industry infrastructure technology or momentum. Exotic architectures are more expensive and have limited title and content support.
2. These approaches do not take advantage of recent advances in technology that give better results at lower cost.
3. They have limited development tool support which limits the range and depth of titles that will be produced.
4. Title development and publishing costs can not be easily leveraged into other markets or platforms.
5. They rely on a single method of information delivery for digital content (CD-ROM) and do not provide a way for the user to save information about who they are and what they have done.

The Opportunity

Tandy has conducted market research on the home information appliance market since 1984. The purpose of the research was to provide insight into the needs and desires of home consumers to improve our personal computer offerings to the home. Many of the pioneering advances Tandy has made in home computing technology have resulted from those ongoing studies. At the same time we were improving personal computing for the consumer, we also realized that the form factor and operational paradigm of the PC would not work for a significant percentage of home consumers.

In 1985, armed with 65 years of experience in the consumer electronics business and having played a principle role in pioneering the personal computer industry, we set out to define the perfect electronic information appliance for the 1990's. Our targets were very aggressive: a mass consumer information product designed to achieve a greater than 25% household penetration over time. Other successful consumer products, like CD and video cassette recorders, typically start with rather modest penetration in the first year (years) then show consistent growth as awareness and title support build. For example, CD-Audio sold 35,000 units, and VCR 10,000 units worldwide in their introductory years. This must be designed as a long term program that can take advantage of current technology and the industry infrastructure while providing the flexibility to grow over time.

We studied what the consumers liked about personal computers and what they did not like. We asked them what kinds of things they do at home, who does them, when they do them, and where in their home these activities take place. We asked them what they would like to do if they had the ability to do anything they wanted. We studied information on the buying habits of our 40 million customers and got direct feedback from our various selling divisions within Tandy.

From our research and experience, we formulated a list of factors that are key to the success of such a product. These factors include attributes that are important to the consumer as well as the title developer. For the consumer, the key factors for success are:

1. Simplicity in learning and operation - The user must be able to immediately understand the product and get much more benefit than the effort required to use it. The design model was to make the products easier to use than a VCR.
2. Compelling content and application - Our studies have consistently confirmed that we need a wide variety of high quality, content-based titles. The principle dimensions for successful titles are:
 - a. Fun
 - b. Information
 - c. Learning

Some titles may focus on a single dimension. We expect most titles to encompass all three elements. Adults and children in the research studies consistently point out the driving factors as a fun way to learn, having fun and getting something out of it (more than just a video game). The titles must have good production quality (quality of the content presentation), depth (measured by time and number of sessions that the user's interest is maintained), and interactivity (the level of responsiveness to user direction and control).

3. Availability - This product class creates a unique experience for the consumer and they must have a personal encounter with it to understand, appreciate, and make a decision about it. This means local availability in a wide variety of channels, under multiple brands available nationwide (and worldwide).
4. Value - The product and title pricing must be commensurate with the perceived benefit of the system. The pricing strategy must be based on consumer pricing models rather than computer models.

Since the most critical factor in the success of products in this category is software/title support, we involved the software and publishing industry in the design process. In 1989, Tandy invited a group of key executives from the software industry to participate in the design and market planning process. Tandy and Microsoft, together with key participants from the software industry formed a cooperative effort to create the perfect balance between consumer market requirements and advanced consumer and computer technologies. We dubbed the project with the code name "Gryphon". By January of 1991, 20 software companies and several other hardware companies were involved in

completing the specification for the platform. By the time the specification was finalized in the fall of 1991, over 65 software and content publishing companies had participated in the program. During the program we conducted three consumer tests to identify the principle uses and compelling reasons to buy and use the products, fine-tune the design parameters, and develop appropriate nomenclature and positioning. We identified the key titles that will drive the product into the marketplace and the software developers and publishers went to work to bring those titles to market.

The result of this effort is the launch of a new generation of information products for the home. The first products will be targeted initially to families with children in the 5-17 age group with a tendency to lead in taking advantage of new technologies. The product is positioned and described as:

A Fun, Informative, Learning Experience for the Whole Family Anytime You Want It.

Consumers have universally described the compelling reasons to own such a product as a fun way to learn, or having fun while learning something -- more to it than a video game. It has something for everyone in the family. It is available anytime you want the experience. With a serious interest in improving education and literacy in the US, many consumers we talked to felt that the learning advantages of such a product alone would justify the investment. The more fun it is the more it will be used; giving greater benefits in learning. Of course, many feel that it is simply a better way to have fun.

The product will be available in a wide variety of channels, under different brands and styles, so we need a way to identify members of this product in the market place. Tandy created a platform name and a distinctive logo to identify compatible products. The name is **Video Information System (VIS)™**.

The studies also indicated that the typical consumer will use the product in the living or family room. This has significant implications for the product design. The display and audio capabilities have to match the other products found in that environment. The user controls have to be optimized for the environment and distances involved in typical operation.

Several groups in the target market are particularly attracted to a product with these capabilities. The current concern over educational quality and literacy has created sensitivity to products that improve educational performance and literary skills. The child literacy factor alone may account for a significant portion of VIS's success. There are also special needs groups that will benefit from VIS. There are 2 million families in the US that have children with clinical reading problems caused by dyslexia. VIS performs the same functions as the computer assisted solutions costing over \$2,000. The 1992 titles list for VIS includes 26 children's reading development and classic literature titles and 11 other early learning titles. This does not include the reference and game titles that have educational elements or the learning titles for older children, adolescents, and adults.

Video Information System Product Definition

Video Information System is a information and application delivery system for the home. It is a way for the consumer to tap into the wealth of information and functionality the digital information age brings. The external product design is very simple. It is intended to fit comfortably in the entertainment center or placed as a set-top TV device. Its primary function initially will be a VIS title player. That is, you insert a VIS disc or cartridge and it "plays" the title. Over time other methods of delivering digital information to the home will evolve and VIS is designed to take advantage of these other forms of information and application delivery as they become available to the consumer. The basic VIS product can be described as follows:

Display:	Standard Television (RF, Composite, or S-Video inputs)
Audio:	Stereo audio connections to TV or Stereo
Controller:	Simplified Infra-Red Remote Control (one standard, 2nd optional controller IR or wired)
Storage Media:	CD-ROM Save•It™ Cartridge
Content:	Full featured 26 volume multimedia encyclopedia (Compton's Multimedia Encyclopedia) Titles Sampler

To the consumer this is a very simple device that delivers a very unique experience. In order to create a wide range of compelling experiences, the device must be very easy to develop for and provide a method of leveraging content and applications from and to other markets and platforms.

While the consumer doesn't care what's on the inside, the software and publishing industry does. The most complex and expensive part of these consumer oriented content-based titles is the acquisition and preparation of the information itself. Since this platform was developed in cooperation with the software industry, it should be no surprise that VIS provides a unique opportunity to leverage the same content into other markets and platforms. The developer can use the same content creation tools, software development systems and software, and even create titles that will run on different products targeted to different markets.

To the software developer VIS is a dream machine. VIS delivers the performance of a Multimedia PC, compatibility with existing software development tools and content, and new capabilities that deliver consumer quality information, interactivity, and ease of use. VIS includes capabilities like:

1. VGA/MCGA compatible video modes on a TV display
2. New video modes supporting up to 16 million colors
3. The ability to mix standard VGA with RGB video modes
4. Hardware assisted animation processing

5. Three types of digital audio (CD-Audio, synthesized-MIDI, and waveform) played simultaneously to create unique quality, real-time effects, and interactivity.
6. Removable storage (Save•It Cartridge)
7. Can use DOS, Windows, and Multimedia PC software and content (with some limitations)
8. Uses existing development tools as well as VIS optimized versions of common software tools

This design approach provides a means of bringing the latest advances in interactive multimedia technology and methodology from the computer industry to a low cost product optimized for the mass consumer marketplace. The capabilities, performance and low cost of VIS are achieved by a highly efficient and highly integrated architecture, custom semiconductors and firmware designed and developed by Tandy that maintains appropriate compatibility with it's relatives in the computer industry while providing the features, performance, and value required by home consumers. Microsoft has created a unique operating environment for VIS that also provides essential compatibility with MS-DOS and Windows while optimizing the operation and performance for demanding consumer applications. Tandy's technology coupled with Microsoft's operating software technology provides a truly unique combination of compatibility with existing computer standards for the developer while providing a simple yet powerful product for the consumer.

Industry Strategy

Those products that have the broadest industry support and availability are those most likely to be accepted by the general consumer marketplace. When products are available from multiple sources and through a variety of selling channels, the consumer feels more confident that they are making an investment that will be supported over time. This is especially true when the product represents a new product category.

The VIS strategy is to enlist and involve wide participation from the consumer, computer, and publishing industries. With the involvement of multiple participants, the consumers and the participants themselves must be assured of compatibility and interchangeability among the various products. This is a very successful model in the consumer industry. This provides for a common base platform level while providing for innovation and competition between individual products and industry participants. To facilitate industry wide participation in the VIS platform, Tandy and Microsoft are licensing their respective proprietary technologies to other manufacturers to build VIS products. Tandy is also making their custom components available to other manufactures that wish to minimize their initial investment and risk involved in semiconductor and subsystem design and development.

The success of VIS will be determined by the quality and variety of titles it delivers. The software and publishing industry has already embraced VIS as a principle consumer

platform. Tandy's strategy is what we refer to as the Independent Software Vendor (ISV) model to enlist support. This differs significantly from the "studio model" described previously. Under the ISV model, a technology and business plan is formulated and implemented that provides the tools and incentives necessary to build a thriving, competitive software and publishing industry independent of a single manufacturer or single source of funding and control. The philosophy is that if you develop the right program and technology, you can enlist developers and publishers to develop titles on their own based on their area of expertise. The developer/publisher is not paid to do it, in fact they have invested their own resources and talents in developing titles. This provides a much greater variety of titles and styles, and a much higher quality of title since they must compete to get a return on their investment. In fact, one way of gauging a new program of this magnitude is to assess the acceptance from the ISV community. If you have to struggle to get support or if you must fund title development, perhaps the program needs to be re-examined. If the platform gets wide acceptance in the software and publishing community, then the platform has a higher chance of success.

In the spring of 1991, Tandy began providing key parts of the architecture to ISV's for study in the form of emulation boards for standard PC's. In the fall of 1991, Tandy began providing full PC based VIS development systems to ISV's and publishers. We completed a study that itemized what were considered to be the driving titles for this product platform and shared this information with the ISV community. We then began asking for title commitments. As of August 1992, we have received commitments from over 50 companies representing over 100 titles for delivery in 1992. This represents a significant industry investment in the VIS platform and serves as a strong confirmation of the product design and program strategy.

Consumers can identify VIS products by the distinctive VIS logo found on licensed hardware and software products. The VIS logo provides a simple way for customers to identify products, titles and accessories that are compatible with their other VIS products. All VIS hardware products must be licensed and carry the logo. The software license is optional, however, non-licensed may not carry the VIS logo and may not use certain proprietary technology and property supplied for licensed titles by Tandy. At this time, all titles confirmed for 1992 are expected to be licensed.

Distribution

VIS is intended to be available in a variety of reselling channels. In the initial stages of the product life cycle, the hardware and software products will probably be sold in the same reselling channels. Over time, we expect the software to be sold in channels that are suited to delivering a large number of titles and may not be associated with hardware selling channels.

In 1992, VIS products will be sold nationwide in consumer electronics retailers and department stores. Tandy will carry VIS products in all of its consumer electronics retail channels representing over 5,000 company owned outlets. VIS products are also

expected to be carried by participating Tandy dealer and franchise stores representing 2,000 outlets. In addition, Zenith Electronics Corporation will sell VIS products under the Zenith brand through their participating dealers and distributors. The software will be primarily distributed by software product distributors or through direct purchase by the retailer. Two software distributors are expected to participate in 1992. Tandy and other consumer electronics manufacturers are expected to launch VIS products in Europe in 1993.

Video Information System, VIS and Save-It are trademarks of Tandy Corporation. The absence of a [®] or a [™] in connection with the mark identifying products of other vendors does not indicate the absence of registration of those marks.

Information on Title Development and Publishing for VIS

Software developers and publishers interested in producing titles for VIS may request a set of VIS software developer specifications and guidelines by contacting Tandy:

Dennis Tanner
Director, Strategic Software
916 One Tandy Center
Fort Worth, Texas 76102
Phone: 817-390-3477
Facsimile: 817-878-6669

Software developers may purchase a VIS development kit which includes a set of emulation boards that can be installed in a personal computer along with development software. The kit includes hardware and software to connect the development system to the VIS system to assist in testing and diagnosis. Tandy will also provide VIS development systems installed and tested in a Tandy personal computer for VIS development at special developer prices. In addition to development systems, there are a variety of development and authoring tools available for VIS software development from other companies. Two authoring and development software companies have special versions of their standard authoring products optimized for VIS development. They are:

Guide Publishing Tools for VIS from OWL International
IconAuthor from Aimtech

Both of these companies have announced special offers for VIS developers.

VIS Titles Committed for 1992 - Alphabetical by Category

(Titles authorized for disclosure as of August 18, 1992)

Learning Titles

A Long Hard Day on the Ranch - *Discis Knowledge Research*
Aesop's Fables - *Discis Knowledge Research*
Aesop's Fables - *EBook*
Beauty and the Beast - *EBook*
Cinderella - *Discis Knowledge Research*
Future Classics - *Saddleback Graphics*
Goldilocks and the Three Bears: English - *Syracuse Language Systems*
Goldilocks and the Three Bears: Spanish - *Syracuse Language Systems*
Heather Hits Her First Home Run - *Discis Knowledge Research*
Just Grandma and Me - *Broderbund*
Learn to Play: The Police - *Intuitive Systems*
Millie's Math House - *EdMark*
Moving Gives Me a Stomach Ache - *Discis Knowledge Research*
Mud Puddle - *Discis Knowledge Research*
Mutnoid Math Challenge - *Legacy*
Mutnoid Word Challenge - *Legacy*
Our House featuring The Family Circus - *Con-Text Systems*
Paper Bag Princess - *Discis Knowledge Research*
Peter and the Wolf - *EBook*
Peter Rabbit - *Discis Knowledge Research*
Play It By Ear - *Con-Text Systems*
Playing with Language: English - *Syracuse Language Systems*
Playing with Language: French - *Syracuse Language Systems*
Playing with Language: German - *Syracuse Language Systems*
Playing with Language: Japanese - *Syracuse Language Systems*
Playing with Language: Spanish - *Syracuse Language Systems*
Rick Rabbit, Adventures in Early Learning - *Integrated Systems*
Sail With Columbus - *Intuitive Systems*
Scary Poems for Rotten Kids - *Discis Knowledge Research*
Sleeping Beauty - *EBook*
"Talking" Stepping Stones Bonus Pack - *CompuTeach*
Tale of Benjamin Bunny - *Discis Knowledge Research*
The Cask of Amontillado - *Discis Knowledge Research*
The Line and Shape Eater - *MediaRight Technology/Cragsmoor Interactive*
The Necklace - *Discis Knowledge Research*
The Night Before Christmas - *Discis Knowledge Research*
The Star Child - *EBook*
The Tell Tale Heart - *Discis Knowledge Research*
Thomas' Snowsuit - *Discis Knowledge Research*
What Was That? Wild Animals! - *GTE ImagiTrek*
White Horse Child - *EBook*

Fun Titles

Adventures in Musicland - *Midisoft Corporation*
Amazon - *Access Software*
Bugaboo - *Top Ten Software*
CD+G - *Intuitive Technologies*
ChessNet - *Masque Publishing*
Children's Songs I - *Silk Ear*
Children's Songs II - *Silk Ear*
Children's Songs III - *Silk Ear*
Christmas Songs I - *Silk Ear*
Christmas Songs II - *Silk Ear*
Chuck Yeager's Air Combat™ - *Electronic Arts*
Easy Street - *Methods and Solutions (MindPlay)*
EcoQuest: Search for Cetus - *Sierra On-Line*
Inspector Gadget - *Azeroth*
Kid Fun - *Methods and Solutions (MindPlay)*
King's Quest V - *Sierra On-Line*
Lemmings - *Psygnosis*
Links - *Access Software*
Loom - *LucasArts Entertainment Company*
Masque Blackjack - *Masque Publishing*
Masque Video Poker - *Masque Publishing*
Meeting of Minds™ - *The JLR Group*
Microleague Baseball - *Con-Text Systems*
Microleague Basketball - *Con-Text Systems*
Microleague Football - *Con-Text Systems*
Mixed Up Mother Goose - *Sierra On-Line*
Music Box - *Midisoft Corporation*
Music City - *Midisoft Corporation*
Mosaic Magic - *KinderMagic*
My Paint - *Saddleback Graphics*
Race the Clock - *Methods and Solutions (MindPlay)*
Rodney's Fun Screen - *Activision*
The 7th Guest - *Virgin Games*
Shelly Duval's It's a Birds Life - *Sanctuary Woods*
Sherlock Holmes: Consulting Detective 1 - *Icom Simulations*
Sherlock Holmes: Consulting Detective 2 - *Icom Simulations*
Space Quest IV - *Sierra On-Line*
The Manhole - *Activision*
Victor Vector and Yondo: The Vampires Coffin - *Sanctuary Woods*

Information Titles

1992 Time Compact Almanac - *Compact Publishing*
American Heritage Illustrated Encyclopedic Dictionary - *Xiphias*
American Vista Multimedia Atlas - *Applied Optical*
Astrology Source - *Multicom*
Atlas of US Presidents - *Applied Optical*
Basic Woodworking - *Intuitive Technologies*
Berlitz's Cruise Travel Planner - *CruiseWatch*
Better Homes and Gardens Healthy Cooking - *Multicom*
Bible Lands, Bible Stories - *Con-Text Systems*
Compton's Multimedia Encyclopedia - *Compton's New Media*
Encyclopedia of Animals - *Applied Optical*
Encyclopedia of Dinosaurs - *Applied Optical*
Great Lives™: Interactive Portraits™ of American Heroes - *The JLR Group*
Home Economics Volume 1 - *Intuitive Systems*
National Audobon Society's "The Secrets of Hosea Freeman" - *Top Ten Software*
New Basics Cookbook - *Xiphias*
